13. SUPPLEMENTARY NOTES					
14. ABSTRACT Prostate cancer (PCa) is the most common cancer and the second leading cause of cancer death among men in the United States. Considering that PCa development requires the coordination of many genes, it is expected that simultaneous evaluation of multiple genetic variants can improve the statistical power to detect additional PCa risk variants. Recent improvements in analytical methods and computation make it feasible to search for gene-gene interaction of SNPs in the genome. We hypothesized that multiple sequence variants in the genome may interact to increase PCa risk. These variants may or may not have known main effect on PCa risk and can be better detected by systematically evaluating gene-gene interactions for SNPs in the genome. We utilized data from an existing GWAS of a large NCI Cancer Genetic Markers of Susceptibility (CGEMS) study to systematically discover gene-gene interactions in the genome. We identified pairs of SNPs that interact with each of the thirty-two known risk SNPs on PCa risk using logistic regression. And we confirmed the interaction for ~300 pairs of SNPs in another case-control study population in Sweden (CAPS) (P<0.05).

INTRODUCTION

Prostate cancer (PCa) is the leading cancer among men in the United States, and is a disease with strong genetic susceptibility. The genetic susceptibility is due to the inheritance of multiple sequence variants, majorly in the form of single nucleotide polymorphisms (SNPs). Most current genetic studies focus only on the single SNP association studies. In contrast, few studies have explored the role of interactions of multiple SNPs with PCa risk, due to limited statistical approaches available to study interactions in a genome-wide level. In fact, gene-gene interaction is the norm rather than exception for complex diseases such as PCa. Inference from tumorigenesis and results from genetic modeling studies suggest that multiple susceptibility genes, either additively or multiplicatively, determine individual risk to PCa. The importance of gene-gene interaction is also supported by empirical evidence from model organisms and human studies. Results from simulation studies suggest that simultaneous evaluation of multiple genetic variants can improve the statistical power to detect additional PCa risk variants and can be more fruitful than traditional approaches that exclusively focus on main effects³⁴. It is expected that additional PCa risk variants will be identified using gene-gene interaction analyses.

In this DOD funded proposal, we propose to 1) identify SNPs in the genome that interact to have stronger effects on PCa risk in the CGEMS GWAS data, 2) confirm the gene-gene interaction effect on PCa risk identified from the CGEMS study in 1,000 PCa cases and 1,000 controls in CAPS, 3) further confirm the gene-gene interaction effects on PCa risk for pairs of SNPs implicated in Aim 2 among the remaining 1,893 cases and 781 controls in CAPS, and 4) fine map the genomic regions where SNPs have been confirmed to have a strong gene-gene interaction effect on PCa risk among all 2,893 cases and 1,781 controls in CAPS.

BODY

Approved Statement of Work:

STATEMENT OF WORK

We will take advantage of two existing large study populations to test this hypothesis. The first study population is the NCI Cancer Genetic Markers of Susceptibility (CGEMS) study, where genome-wide data are available for 1,172 PCa case patients and 1,157 control subjects of European Americans descent. The second study population is our large population-based case-control study from Sweden (CAPS), with 2,893 PCa patients and 1,781 control subjects. These two large study populations are necessary to have sufficient statistical power to detect true interactions in the genome and to remove false positives using a multiple-stage study design.

Aim 1. Identify SNPs in the genome that interact to have stronger effects on PCa risk in the CGEMS GWAS data.

Step by step method and expected results

- 1) (**Months 1**) Preparation of the study, including IRB and other logistic issues.
- 2) (**Months 2**) Pre-association analysis and imputation of all the SNPs in the genome.
- 3) (**Months 3-12**) Logistic regression analysis to identify pairs of SNPs that interact to have stronger effects on PCa risk.
- 4) (**Months 3-12**) Bayesian epistasis association mapping (BEAM) to identify pairs of SNPs that interact to have stronger effects on PCa risk.

Outcome and deliverables

We will identify pairs of SNPs in the genome whose interaction terms reach $P < 0.001$. Based on the results of genome-wide searches for SNPs that interact with rs1447295 at 8q24, we expect to identify ~450 independent SNPs that interact with each of the twelve known PCa risk SNPs. In addition, we expect to identify additional SNPs that have stronger two-way or three-way interaction effects on PCa risk from the BEAM analysis. These SNPs, estimated to number around ~5,000, will be selected for further confirmation in Aim 2.

Aim 2. Confirm gene-gene interaction effects on PCa risk identified from the CGEMS study in 1,000 PCa cases and 1,000 controls in CAPS

Step by step method and expected results

- 1) (**Months 6-16**) Genotype ~5,000 SNPs among 1,000 cases and 1,000 controls in CAPS using iSELECT of Illumina.
- 2) (**Months 17-20**) Analyze data using logistic regression and BEAM methods to remove false positives identified in Aim 1 and obtain a smaller subset of SNPs that most likely represent true interaction for further confirmation in larger samples.

Outcome and deliverables

Most of the false positive interactions will be removed from this aim. We expect 125 pairs of SNPs in this stage will have $P < 0.05$ and have the same direction of interaction effect as in the CGEMS data [(5,000 x 0.05)/2]. These SNPs will be selected for further confirmation in Aim 3. The actual number of SNPs may be higher if there are more true interaction effects in the genome.

Aim 3. Further confirm the gene-gene interaction effects on PCa risk for pairs of SNPs implicated in Aim 2 among the remaining 1,893 cases and 781 controls in CAPS

Step by step method and expected results

- 1) (**Months 21-24**) Genotype 125 SNPs among 1,893 cases and 781 controls in CAPS using iPLEX of Sequenom.
- 2) (**Months 25-28**) Analyze data using logistic regression and BEAM methods to remove false positives identified in Aim 1 and obtain a smaller subset of SNPs that most likely represents true interaction for further confirmation in larger samples.

Outcome and deliverables

We will use a stringent genome-wide significance level from the joint analysis ($P < 10^{-8}$) to declare significant interaction. In fact, considering that 12 genome-wide associations were performed, it is more conservative to use the cutoff of $P < 10^{-9}$. The actual number of SNPs whose interactions meet the criteria depends on the number of true interactions in the genome with the OR detectable in our study.

Aim 4. Fine map the genomic regions where SNPs have been confirmed to have strong gene-gene interaction effect on PCa risk among all 2,893 cases and 1,781 controls in CAPS

Step by step method and expected results

- 1) (**Months 29-30**) Functional SNPs and tagging SNPs will be selected in the genomic region for each of the SNPs implicated in Aim 3.

- 2) **(Months 29-30)** Selected SNPs will be genotyped in 2,893 cases and 1,781 controls of CAPS using iPLEX of Sequenom.
- 3) **(Months 31-36)** Fine mapping data analysis will be performed to identify the most strongly associated SNPs (interaction effect) in each of the regions implicated in Aim 3.

Summary report

By July 2011, we will be in the 24th month of this funded project. During the last year, we have completed the following 1) performed genome-wide epistasis analysis of the 20 novel risk SNPs reported 2) tested interaction effect ~7,000 SNPs that were implicated in Aim 1 among 1,500 cases and 1,000 controls in CAPS 3) genotyped ~300 SNPs among 1,893 cases and 3,172 iControls in JHH using iPLEX of Sequenom (genotyping data for iControls are obtained from Illumina Icontrol database (www.illumina.com))

Detailed report

Study population. For Aim 2, we used an existing study population in Sweden (CAPS). The study population used in Aim 3 was from Johns Hopkins Hospital (JHH), which included 1,964 PCa cases and 3,172 control subjects. The cases are Caucasian PCa patients who underwent radical prostatectomy for the treatment of PCa at JHH from January 1, 1999, through December 31, 2008. The control subjects for this population were an independent group of Caucasian individuals from the Illumina iControlDB (iControls) dataset (<http://www.illumina.com/science/icontribdb.ilmn>). In our initial proposal, we planned to use the remaining 1,893 cases and 781 controls in CAPS in Aim 3. However, we think it would be more meaningful if we can confirm the results in a complete independent and larger population.

SNP followed in Aim 2 and Aim 3. For the SNPs that reached a $p < 10^{-3}$ in the CGEMS GWAS analysis in Aim 1, we ran the clumping function implemented in PLINK to get a smaller number of independent SNPs ($r^2 < 0.5$). For Aim 2, a total of 7,029 independent SNPs were identified and analyzed in CAPS population. SNPs that reached a p-value of 0.05 were further followed in the JHH population.

Statistical analysis.

Logistic regression analysis. Recently, more risk SNPs for PCa were reported (1-15). Therefore, we performed additional epistasis analysis between each of the twenty novel risk SNPs (Table 1) and each SNP in the genome, as we did for the initial twelve SNPs we proposed. The epistasis effects were systematically tested by including both SNPs and an interaction term (product of two SNPs) in a logistic regression model. The analysis were implemented in the computer program PLINK. This is computationally feasible because PLINK provides an approximation but faster method (option: -fast-epistasis) to efficiently screen for gene-gene interaction. This test is based on a Z-score for difference in SNP1-SNP2 association (odds ratio) between cases and controls. For pairs of SNPs that reached a liberal P-value ($P < 0.01$), we will also performed a standard logistic regression analysis (option: -epistasis) to identify pairs of SNPs whose interaction terms reached $P \leq 0.001$. Ancestral proportions obtained were included as covariates to minimize the impact of potential population stratification. An additive genetic model was used in the analysis.

Category: Original 12 indicated the 12 SNPs included in the original proposal, New 20 indicate SNPs that were newly reported

m = minor allele, M = major allele.

Results

Multiplicative interactions between one of the thirty-two known PCa risk variants and each SNP in the genome were systematically tested by including both SNPs and an interaction term (product of two SNPs) in a logistic regression model. The top pairs of independent SNPs that interact with each of the 21 novel risk SNPs

($p < 0.001$) except for rs16902094 are listed in Supplementary Table 1. One SNP, rs16902094, is not included in the analysis because it is not characterized in the Hapmap database ([www. Hapmap.org](http://www.Hapmap.org)), and therefore can't be imputed based on CGEM data.

A summary of the number of pairs of SNPs that are significant at $P < 0.05$ and in the same direction of association in the CAPS population is presented in Table 2. The detailed epistasis results for the 6,794 SNPs followed in Aim 2 are presented in Supplementary Table 1.

Table 2. Summary of interaction results in CGEMS and CAPS population

Discussion

Since 2007, genome-wide association studies successfully identified at least 33 PCa risk-associated single nucleotide polymorphisms (SNPs) (1-15). Although those risk-associated SNPs are well replicated in multiple studies, very few studies assess the potential epistasis, or gene-gene interaction between those SNPs and the rest of SNPs reside in the genome. Considering the importance of epistasis, or gene-gene interaction in the initiation of prostate cancer, we carried out a three-stage GWAS study to systematically evaluate the SNPs that interact with each of the 33 known risk SNPs in this funded proposal.

Two of the most notable advantages of our study design ensured the significance of our study. Firstly, it represents the most comprehensive study of gene-gene interaction for prostate cancer. In our initial proposal, 12 known risk SNPs were proposed to be studied. However, during the last two years, 20 more PCa-risk associated SNPs have been reported. Therefore, we also included the newly identified PCa-risk associated SNPs into our main analysis, and performed 20 additional GWAS analysis in year 2. This represents a tremendous important add-on effort to our initial proposal, and ensures our current study is the most comprehensive study on gene-gene interaction for prostate cancer risk, as it includes the evaluation of genes that interact with all the known PCa risk-associated SNPs. Secondly, our study includes a discovery study population, as well as two independent replication populations. Using a GWAS approach to search for gene-gene interaction will generate a large number of significant pairs of SNPs. However, a large proportion of the significant interacted SNPs identified in the discovery dataset are due to multiple testing issues. The most effective approach to remove those false positives and identify the true interacted SNPs is to use a multiple-stage design. The availability of two existing large independent populations to be used in the replication study greatly enhances the significance of our study. Particularly, we used CGEMS, which includes 1,176 PCa cases and 1,101 control subjects as the discovery samples, and use CAPS, which included 1,500 cases and 500 controls, and JHH, which included 2,000 cases and 3,000 controls, as the two confirmation populations. The SNP-SNP interactions replicated in both study populations are more likely to represent true associations.

Table 2 summarized our major results for year 2. A total of 1,757,946 SNPs that passed QC were included in the final analysis for CGEMS. Under the null hypothesis that no true gene-gene interaction exist in our dataset, we would observe ~176 pairs of SNP-SNP interactions ($1,757,946 \times 0.001 = 176$) to be associated with PCa risk. In the CGEMS dataset, we detected more significant interactions for most of the risk SNPs evaluated (# of significant interactions far more than 176, table 2). The excess significant interaction pairs we observed indicated that the true associated SNP-SNP interaction does exist in the CGEMS dataset. More importantly, many of the top-ranking SNP-SNP interactions detected in CGEMS were confirmed in the 2nd independent population of CAPS. Again, if under the null hypothesis of no true gene-gene interaction, the number of significant interactions observed in CAPS would be approximately 5, using a P-value cutoff of 0.05 and with the same direction of association effect (Assuming ~200 tests in CAPS for each of the 32 SNPs, the expected number of significant interactions observed in CAPS under the null would be equal to $200 \times 0.05 / 2 = 5$). As presented in Table 2, except for rs12621278 and rs2735839, the detected number of significant interacted SNPs were all larger than 5. The excess of observed interactions in the 2nd independent population also supported that the findings from our current study are more likely to represent true gene-gene interaction effects.

Based on our current results, we would like to highlight an interaction between one pair of SNPs when considering the possible biological function. The interaction was between rs6983267 at 8q24 Region 3 and rs3739262 in *WISP1* (Supplementary Table 2). This interaction was highly significant in CGEMS ($P = 6.6E-04$) and was confirmed in the CAPS population ($P = 0.048$). The SNP

rs6983267 is located in a genomic region containing the *POU5F1B* gene. The overexpression of *POU5F1B* has been observed in prostate cancer. *POU5F1B* has a similar expression pattern with *POU5F1*, which is known to promote epithelial tumors (16). *POU5F1* encodes a transcription factor, which is activated by the WNT pathway (17). This transcription factor plays a central role in embryonic development, especially during early embryogenesis, and it is necessary for embryonic stem cell pluripotency. This evidence is consistent with the hypothesis that the reactivation of embryonic pathways is involved in prostate cancer progression (18). Taken all those together, we may hypothesize that the significant association of rs6983267 on 8q24 region with prostate cancer may be due to a pluripotency function of *POU5F1B*, but not *POU5F1*. rs3739262 is located in the intron of the *WISP1* gene. The *WISP1* gene belongs to the WNT1 inducible signaling pathway (WISP) protein subfamily, which is a member of the connective tissue growth factor (CTGF) family. *WISP1* gene is downstream in the WNT1 signaling pathway which is involved in malignant transformation. The overexpression of this gene has been observed in colon tumors. Given the above evidence, we hypothesize that *WISP* mediates the *WISP-POU5F1B* interaction by participating in the regulation of the WNT signaling pathway, and in turn regulates the expression of *POU5F1B*.

Several other pairs of interactions are notable, including an interaction between rs7679673 in *TET* and rs6103041 in the *PTPRT* ($P=2.65E-05$ in CGEMS, $P = 0.02$ in CAPS), and an interaction between rs4430796 in *HNF1B* and rs4543871 in *ATF3* ($P=7.2E-04$ in CGEMS, $P= 0.02$ in CAPS). However, to obtain conclusive evidence, we would like to see whether the above interaction effects can be confirmed in the JHH population. Therefore, in year 3, we will analyze and confirm the top ranking SNPs that interact with the known risk SNPs in another independent JHH population (Aim 3). The pairs of SNP-SNP interactions that are confirmed in both the CAPS and JHH populations are more likely to represent true interaction effects. For the confirmed genomic regions, we will also perform fine-mapping studies to identify the most strongly associated SNPs (interaction effect) in each of the genomic regions implicated in Aim 3. Fine-mapping is a powerful approach to identify the most significant association signal and may help to pinpoint the most plausible causal SNP within a genomic region. We expect to generate highly significant results, upon completion the proposed work in year 3. Our study will be one of the first studies to report significant results for SNP-SNP interaction analysis with prostate cancer risk in three large independent populations.

KEY RESEARCH ACCOMPLISHMENTS

- 1) Completed genome-wide logistic regression analysis to identify pairs of SNPs that interact with twenty novel risk SNPs on PCa risk.
- 2) Completed genotyping and analysis of ~6,000 implicated in Aim 1 among 1,500 cases and 500 controls in CAPS.
- 3) Identified and followed ~300 SNPs that are confirmed in Aim 2 in a JHH population, which includes 1,893 cases and 3,172 controls.

REPORTABLE OUTCOMES

- 1) SNPs in the genome that interact with each of the twenty novel PCa risk SNPs with significant interactions ($P \leq 0.001$) (Supplementary Table 1)
- 2) ~300 SNPs that interacted with each of the thirty-two PCa risk SNPs that are confirmed in Aim2 ($P<0.05$). (Supplementary Table 2)

CONCLUSION

- 1) We have made great progress in achieving the goals described in the approved Statement of Work.
- 2) We have identified and confirmed SNPs in the genome that significantly interacts with each of the thirty-two known PCa risk SNPs in two of our study populations.
